

# CEE 680: Water Chemistry

Lecture #3

Intro: Atoms and Isotopes

(Stumm & Morgan, Chapt. 4.9 )

(Pg. 195-202)

Best source for stable isotopes is:

**Eby, Chapter 6, especially pg. 181-186**

# Molarity

- One mole of any substance contains  $6.02 \times 10^{23}$  (Avogadro's number) elementary chemical units (e.g., molecules).
- It is very convenient to measure concentrations in moles, since reactions conform to the law of definite proportions where integer ratios of reactants are consumed (e.g., 1:1, 1:2, etc.) on both a molecular and molar basis.
- It is calculated by:

$$\text{Molarity} = \frac{\text{mass} / L}{\text{GFW}}$$

- Often use M, mM,  $\mu\text{M}$  (molar, millimolar, micromolar)
  - To represent: moles/L,  $10^{-3}$  moles/L,  $10^{-6}$  moles/L

S

# Periodic Table of the Elements

# Normality

- Like molarity, but takes into account the stoichiometric ratios of reactants and products
  - e.g., charge, exchangeable H<sup>+</sup>, exchangeable electrons
- Measured in equivalents per liter (eq/L or equ/L)
  - Or meq/L (=10<sup>-3</sup> eq/L)

$$\text{Normality} = \frac{\text{mass/L}}{\text{GEW}}$$

- And Z is an integer related to the number of exchangeable hydrogen ions, or electrons the chemical has, or its overall charge

$$\text{GEW} = \text{GFW} / Z \quad \text{or} \quad \text{Normality} = \frac{\text{mass/L}}{\text{GFW}} (Z)$$

$$\text{calculated TDS} = \sum \text{Conc.} = 80.55 \frac{\text{mg}}{\text{L}}$$

# Common Constituents

- N, P, and S containing compounds are often expressed in terms of their elemental concentration
- Examples
  - 66 mg of  $(\text{NH}_4)_2\text{SO}_4$  added to 1 L of water
  - 85 mg of  $\text{NaNO}_3$  added to 1 L of water

# Example: element/group conc.

- Consider a solution of Ammonium Sulfate prepared by dissolving 66 g of the anhydrous compound in water and diluting to 1 liter. What is the concentration of this solution in:
  - a) g/L?
  - b) moles/L?
  - c) equivalents/L?
  - d) g/L as sulfate?
  - e) g/L as N?

# Example (cont.)

- a) 66 g/L
- b) The gram formula weight of ammonium sulfate is 132 g/mole. So, using equation 2.7, one gets:
  - $\text{Molarity} = (66 \text{ g/L}) / (132 \text{ g/mole}) = 0.5 \text{ moles/L}$  or 0.5 M.
- c) Without any specific information regarding the use of this solution, one might simply presume that either the sulfate group or the ammonium group will be the reacting species. In either case, Z should be equal to two (product of the oxidation state times the number of groups). So:
  - $\text{Normality} = 0.5 \text{ moles/L} * 2 \text{ equivalents/mole}$
  - $= 1 \text{ equivalent/L}$  or 1.0 N or N/1.

# Example (cont.)

- d) The GFW for sulfate is:

- $$\text{GFW} = 32 + 4 \cdot 16 = 96.$$

- The molarity of sulfate is:

- $$\text{Molarity} = 0.5 \text{ moles}-(\text{NH}_4)_2\text{SO}_4/\text{L} * 1 \text{ mole-}$$
$$\text{SO}_4/\text{mole}-(\text{NH}_4)_2\text{SO}_4$$

- $$= 0.5 \text{ moles-SO}_4/\text{L}$$

- Then, one gets

- $$\text{mass/L} = \text{Molarity} * \text{GFW}$$
$$= 0.5 \text{ moles-SO}_4/\text{L} * 96 \text{ g-SO}_4/\text{mole-SO}_4$$

- $$= 48 \text{ g-SO}_4/\text{L}$$

# Example (cont.)

- e) The GFW for nitrogen is simply 14:

- The molarity of nitrogen is:

- $$\text{Molarity} = \frac{0.5 \text{ moles}-(\text{NH}_4)_2\text{SO}_4/\text{L} * 2 \text{ moles-N/mole}-(\text{NH}_4)_2\text{SO}_4}$$

- $$= 1 \text{ mole-N/L}$$

- Again, one gets:

- $$\text{mass/L} = \text{Molarity} * \text{GFW} = 1 \text{ mole-N/L} * 14 \text{ g-N/mole-N}$$

- $$= 14 \text{ g-N/L or } 14 \text{ g NH}_3\text{-N/L}$$

# Calcium carbonate units

- Used for major ion concentrations in drinking waters
  - Alkalinity
  - Hardness
- Since  $\text{CaCO}_3$  is divalent ( $Z=2$ ) and its GFW is 100 g, its GEW is 50 g
  - 50 g/equivalent or 50 mg/meq
  - 50,000 mg/equivalent

# Atomic Mass I

- One Dalton is defined as the mass of one-twelfth of a Carbon 12 atom
  - Therefore a  $^{12}\text{C}$  weighs exactly 12 Da

$$1\text{Da} = \frac{1}{12} M_{^{12}\text{C}} = \frac{1}{N_A}$$
$$= 1.66053878 \times 10^{-27} \text{ kg}$$

- *Sub atomic particles*
  - $m_{\text{proton}} = 1.007825 \text{ Da}$
  - $m_{\text{neutron}} = 1.008665 \text{ Da}$

# Atomic Mass II

- Mass Defect ( $m_{\text{def}}$ ) and binding energy ( $\Delta E$ ) for a single atom is given by:

$$m_{\text{def}} = m_s - m_b = Zm_p + Nm_n - m_b$$

- where 
$$\Delta E = m_{\text{def}}c^2$$
  - $c$  is the speed of light,
  - $m_s$  is the mass of the separated nucleons
  - $m_b$  is the mass of the bound nucleus
  - $Z$  is the atomic number of the bound nucleus
  - $m_p$  is the mass of one proton
  - $N$  is the number of neutron
  - $m_n$  is the mass of one neutron.

# Atomic Mass III

## ● example: a deuteron

- A deuteron is the nucleus of a deuterium atom, and consists of one proton and one neutron. The experimentally-measured masses of the constituents as free particles are
  - $m_{\text{proton}} = 1.007825 \text{ Da}$ ;  $m_{\text{neutron}} = 1.008665 \text{ Da}$ ;
  - $m_{\text{proton}} + m_{\text{neutron}} = 1.007825 + 1.008665 = 2.01649 \text{ Da}$ .
  - The mass of the deuteron ( ${}^2\text{H}$ , also an experimentally measured quantity) =  $2.014102 \text{ Da}$ .
- The mass difference =  $2.01649 - 2.014102 = 0.002388 \text{ Da}$ .
  - Since the conversion between rest mass and energy is  $931.494 \text{ MeV/Da}$ , a deuteron's binding energy is calculated to be  $0.002388 \text{ Da} \times 931.494 \text{ MeV/Da} = 2.224 \text{ MeV}$ .
