

## CEE 697K

### Environmental Reaction Kinetics

#### Homework #4

- The data below are for the decomposition of Dichloroacetonitrile (DCAN) at pH 7, and 20 C. One column is for an ionic strength of 0.01 M (mostly NaCl), and the other for 0.03 M. Analyze these data and make any conclusions you can regarding the nature of the hydrolysis reaction of DCAN.

| Time (hours) | DCAN Concentration ( $\mu\text{g/L}$ ) |            |
|--------------|--|------------|
|              | I = 0.01 M                             | I = 0.03 M |
| 0.00         | 44.49                                  | 44.74      |
| 0.75         | 41.10                                  | 42.29      |
| 1.50         | 43.73                                  | 41.64      |
| 2.50         | 38.84                                  | 37.87      |
| 3.50         | 38.27                                  | 38.45      |
| 6.50         | 29.22                                  | 31.97      |
| 9.50         | 26.94                                  | 29.17      |
| 19.50        | 16.25                                  | 19.31      |
| 24.50        | 12.66                                  | 16.44      |
| 29.50        | 9.52                                   | 13.49      |
| 41.50        | 5.42                                   | 10.06      |
| 69.50        | 1.55                                   | 3.83       |
| 116.50       |  | 2.05       |

- Prepare 1<sup>st</sup> order and 2<sup>nd</sup> order graphs based on integral method
  - Conclusion is that 1<sup>st</sup> order in DCAN fits best
  - Rate constant goes up as ionic strength goes down
  - Direction and magnitude of ionic strength effects implies that reaction is between a negative species (hydroxide) and a species with a positive center (maybe the carbon on the nitrile).
- Prepare a Hammett Plot for the chlorination of phenol at high pH (i.e., phenate ions). Use all of the rate constants in Figure 13 from Deborde & von Gunten, 2008 [*Water Research* 42:13-51]. To help you with this you should number each carbon and treat the attack on different carbon atoms separately even if they result in the same product. Use the Hammett substituent constants in the attached table. Compare your results with those obtained by Deborde & von Gunten in their Figure 15.

Slope is much less than the one presented by Deborde & vonGunten.

- Use the Hammett Plot prepared for #2, and predict the rate constant for the reaction of chlorine with the phenate ion of 2-amino-4-nitro-5-methyl phenol. Assume that the two unsubstituted carbons (C3 and C6) are the only sites of attack. Estimate the relative rate of attack on these two carbons.

2-amino-4-nitro-5-methyl phenol

|       | position |        |
|-------|----------|--------|
|       | C3       | C6     |
| sigma | 0.89     | -0.67  |
| log k | 1.0029   | 3.1713 |
| k     | 10.1     | 1483.5 |

$\text{M}^{-1} \text{s}^{-1}$

Therefore, the overall 2<sup>nd</sup> order rate constant is  $1494 \text{ M}^{-1} \text{s}^{-1}$ , or about  $1.5 \times 10^3 \text{ M}^{-1} \text{s}^{-1}$ , with slightly more than 99% of the attack at the #6 carbon.

## Hammett Substituent Constants

| Substituent                                    | $\sigma_p$ | $\sigma_m$ | $\sigma_o$ | $\sigma_{p+}$ | $\sigma_{+m}$ | $\sigma^*$ | R     | F     |
|--|------------|------------|------------|---------------|---------------|------------|-------|-------|
| -N(CH <sub>3</sub> ) <sub>2</sub>              | -0.83      | -0.16      | -0.36      | -1.70         |               |            | -0.98 | 0.15  |
| -O <sup>-</sup>                                | -0.81      | -0.47      | -1.10      |               |               |            |       |       |
