*Organic Compounds in Water and Wastewater*

PCBs and other HOCs:  
 Volatilization & other processes

Lecture #36

CEE 697z - Lecture #36

Volatilization: The two film theory

CEE 697z - Lecture #36

## Two film model

Universal Gas Law

$$\frac{n}{V} = \frac{P}{RT_a}$$

Molar concentration

- ▶ Flux from the bulk liquid to the interface

$$J_l = K_l(c_i - c_l)$$

- ▶ Flux from the interface to the bulk gas

Mass transfer  
velocities (m/d)

$$J_g = \frac{K_g}{RT_a}(p_g - p_i)$$

- ▶ And the K's are related to the molecular diffusion coefficients by:

$$K_l = \frac{D_l}{z_l}$$

$$K_g = \frac{D_g}{z_g}$$

## Two film theory (cont.)

- ▶ We want to be able to relate flux to bulk air and water concentrations
  - ▶ interface concentrations cannot be directly measured

$$J = v_v \left( \frac{p_g}{H_e} - c_l \right)$$

- ▶ to do this we must substitute expressions for the interface concentrations

CEE 697z - Lecture #36

## Air/Water Equilibrium

### ▶ Henry's Law

▶ or 
$$H_e \equiv K_H = \frac{p_i}{x_i}$$

$$H_e \equiv K_H = \frac{p_i}{c_i}$$

▶ CEE 697z - Lecture #36

## Whitman's 2 film model (cont.)

▶ According to Henry's law:

$$p_i = H_e c_i$$

▶ And relating this back to the bulk concentration

$$p_i = H_e \left( \frac{J_l}{K_l} + c_l \right)$$

Recall:  $J_l = K_l (c_i - c_l)$

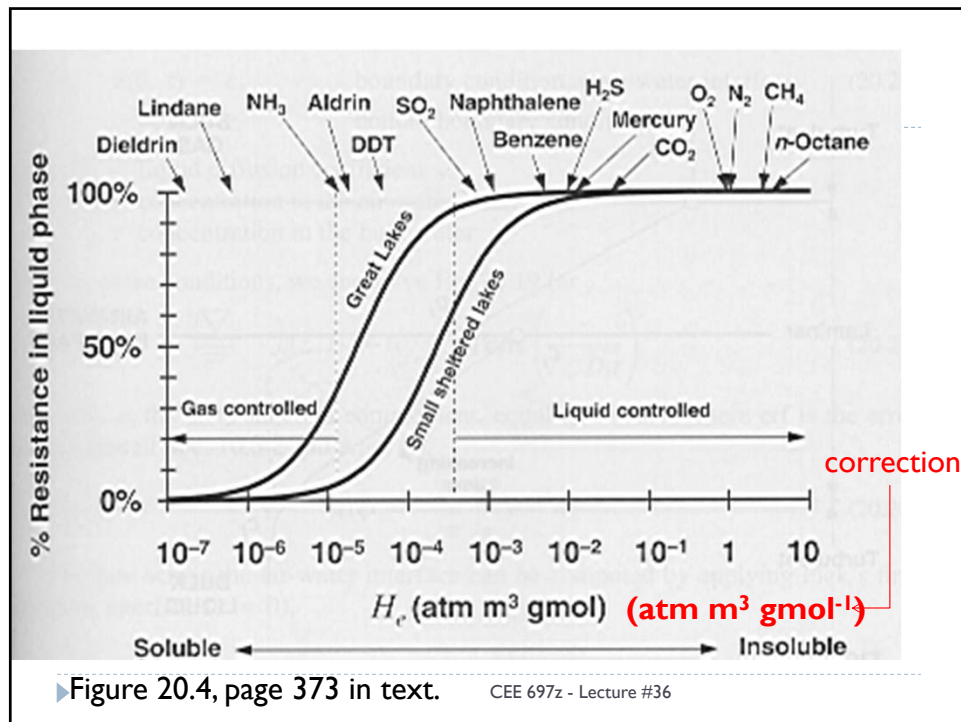

So:  $c_i = \frac{J_l}{K_l} + c_l$

▶ now solving and equating the fluxes, we get (pg. 371 in text):

The net transfer velocity across the air-water interface (m/d) sometimes represented as  $K_{oi}$

$$\frac{1}{v_v} = \frac{1}{K_l} + \frac{RT_a}{H_e K_g}$$

▶ CEE 697z - Lecture #36

## Two Film Volatilization Model

▶ Jeremiason's equation 
$$k_{vol} = \frac{K_{ol}}{h} f_w$$

▶ Same as Chapra's 
$$k_v = \frac{v_v}{H_1} f_{d1}$$

▶ Where:

$$\frac{1}{K_{ol}} = \frac{RT}{k_a H} + \frac{1}{k_w}$$

## Estimating 2-film parameters

- ▶ The gas film coefficient

$$k_{a,H_2O} = 0.2u_{10} + 0.3$$

- ▶ The liquid film coefficient

$$k_{a,PCB} = k_{a,H_2O} \left( \frac{D_{PCB,air}}{D_{H_2O,air}} \right)^{0.61}$$

$$k_{w,CO_2} = 0.45u_{10}^{1.64}$$

$$k_{w,PCB} = k_{w,CO_2} \left( \frac{Sc_{PCB}}{Sc_{CO_2}} \right)^{-0.5}$$

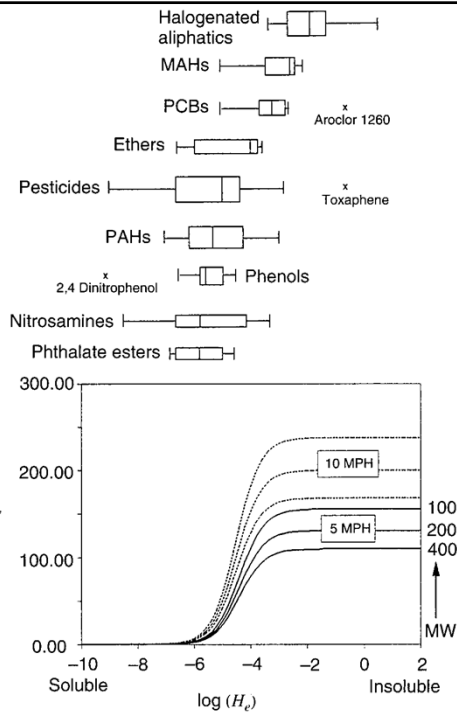

Kinetic viscosity: molecular diffusivity

$$Sc = \frac{\mu}{\rho \cdot D_v} \quad \text{Schmidt Number}$$

CEE 697z - Lecture #36

## Effect of $U_w$ and $H_e$

- ▶ Chapra, pg. 730

Bamford, H.A., Poster, D.L. and Baker, J.E. (1999) Temperature dependence of Henry's law constants of thirteen polycyclic aromatic hydrocarbons between 4 degrees C and 31 degrees C. *Environmental Toxicology and Chemistry* 18(9), 1905-1912.

## Determination of $H_e$

### ▶ The gas-stripping device:

- ▶ a 122-cm by 15.2-cm diameter glass reactor, a 5-mm glass impactor, a 5- $\mu$ m pore-size air stone, and a 500-ml glass gas washing bottle.

### ● Procedure:

- The apparatus was filled to a depth of 83 cm with 10 L of deionized water.
- Between 130 ml/min to 200 ml/min of compressed air was passed through a hydrocarbon trap to remove possible contaminants and through a gas washing bottle to saturate the air with water vapor prior to entering the reactor through the air stone mounted at the bottom of the water column.

CEE 697z - Lecture #36

Bamford, H.A., Poster, D.L. and Baker, J.E. (1999) Temperature dependence of Henry's law constants of thirteen polycyclic aromatic hydrocarbons between 4 degrees C and 31 degrees C. *Environmental Toxicology and Chemistry* 18(9), 1905-1912.

## Det. of $H_e$ (cont.)

### ▶ Procedure (cont.):

- ▶ Air exiting the reactor passed through the impactor to remove aerosols created by breaking bubbles, then through a cylindrical polyurethane foam plug (PUF) housed in a glass column to capture vapor-phase compounds.
- The efficiency and application of PUF to absorb hydrophobic organic contaminants (HOCs) have been evaluated in several studies
- Water samples (50 ml) were drawn through a Teflon stopcock located at the base of the reactor.
- During each experiment, simultaneous air and water samples were collected every 24 to 48 h for 6 to 12 d.

CEE 697z - Lecture #36

## Det. of $H_e$ (cont.) with QC

- ▶ The entire system was located in a controlled environment room, where the lights remained off during each experiment to minimize any loss of compounds to photodegradation.
- ▶ Compound mass balances were determined to insure analytes were not lost to degradation or to leaks in the system
  - ▶ Mass recoveries for the compounds ranged between 85% and 112% of the initial mass added.

## Det. of $H_e$ - Chemical Analysis

- ▶ **Extraction:** The PUF samples were Soxhlet extracted for 24 h with ~150 ml of chromatographic grade petroleum ether. Extracts were reduced to <3 ml by rotary evaporation, switched to hexane, and further concentrated under a gentle stream of clean  $N_2$  to a final volume of ~1 ml. Each water sample was solvent extracted three times with 10 ml of hexane in a separatory funnel, and combined extracts were dried with  $Na_2SO_4$  and reduced by rotary evaporation to ~1 ml in hexane. The concentrated samples were transferred to amber autosampler vials and sealed with Teflon caps and stored in the dark at 4°C until analysis.
- ▶ **Analysis:** All compounds were analyzed by GC/MS (HP 5890 GC and HP 5972 Mass Selective Detector) operated in selective ion monitoring (SIM) mode. The column was 30 m in length, 0.25 mm i.d. with a cross linked 5% phenyl-methyl silicone film thickness of 0.25  $\mu m$ .
  - ▶ Identification of individual compounds was based on the retention times of the parent ion of each compound relative to the retention time of a calibration standard. Internal standards, consisting of deuterated compounds were added to the calibration standard and each sample prior to GC/MS analysis. Internal standards were used to calculate relative response factors for each analyte by comparing a known mass of analyte in the calibration standard to the known mass of a particular internal standard.

## Conclusions on PCB fate

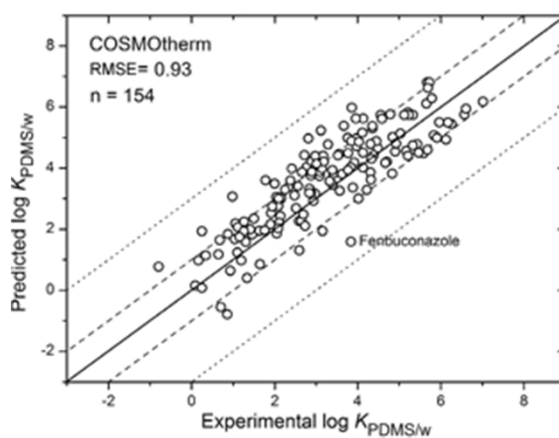

The environmental fate and transport of PCBs is largely governed by their physical-chemical characteristics, properties which vary considerable across the spectrum of species included in this family of chemicals. Chief among these properties are the octanol-water partition coefficient, a measure of the potential to associate with particles, and the Henry's Law constant, a reflection of the partitioning of the chemical between air and water. In general, high MW PCBs are strongly associated with particles and low MW PCBs are more strongly partitioned to the atmosphere.

As a result, fish consumption advisories are common in Michigan and other states.

Water body	Species	Contaminant(s)	General Population								Women & Children
