

Strong Security for Active Networks

S. Murphy, E. Lewis, R. Puga, R. Watson and R. Yee

Presenter: Jianhong Xia

10/08/2002

How Strong Security Is

- ⇒ End-End authentication and integrity protection
- ⇒ Authorization information carried by active packet itself.
 - Enforcement of each node's authorization policy
 - End user controls over access of its own state
 - Node policy takes precedence over active code policy

Outline

- ⇒ Background
- ⇒ Security Requirements
- ⇒ Trust Model/Challenges
- ⇒ SANTS
 - ▣ Components
 - ▣ Authentication
 - ▣ Authorization
- ⇒ Security Architecture
- ⇒ Conclusion

Active Networks Security

--- from S. Murphy's slides

Background

➔ Features of Active Network

- ▣ Rapid deployment of new network services
- ▣ Complex computations to be performed on packets

➔ But, Security Concerns

- ▣ Network operators
- ▣ End users

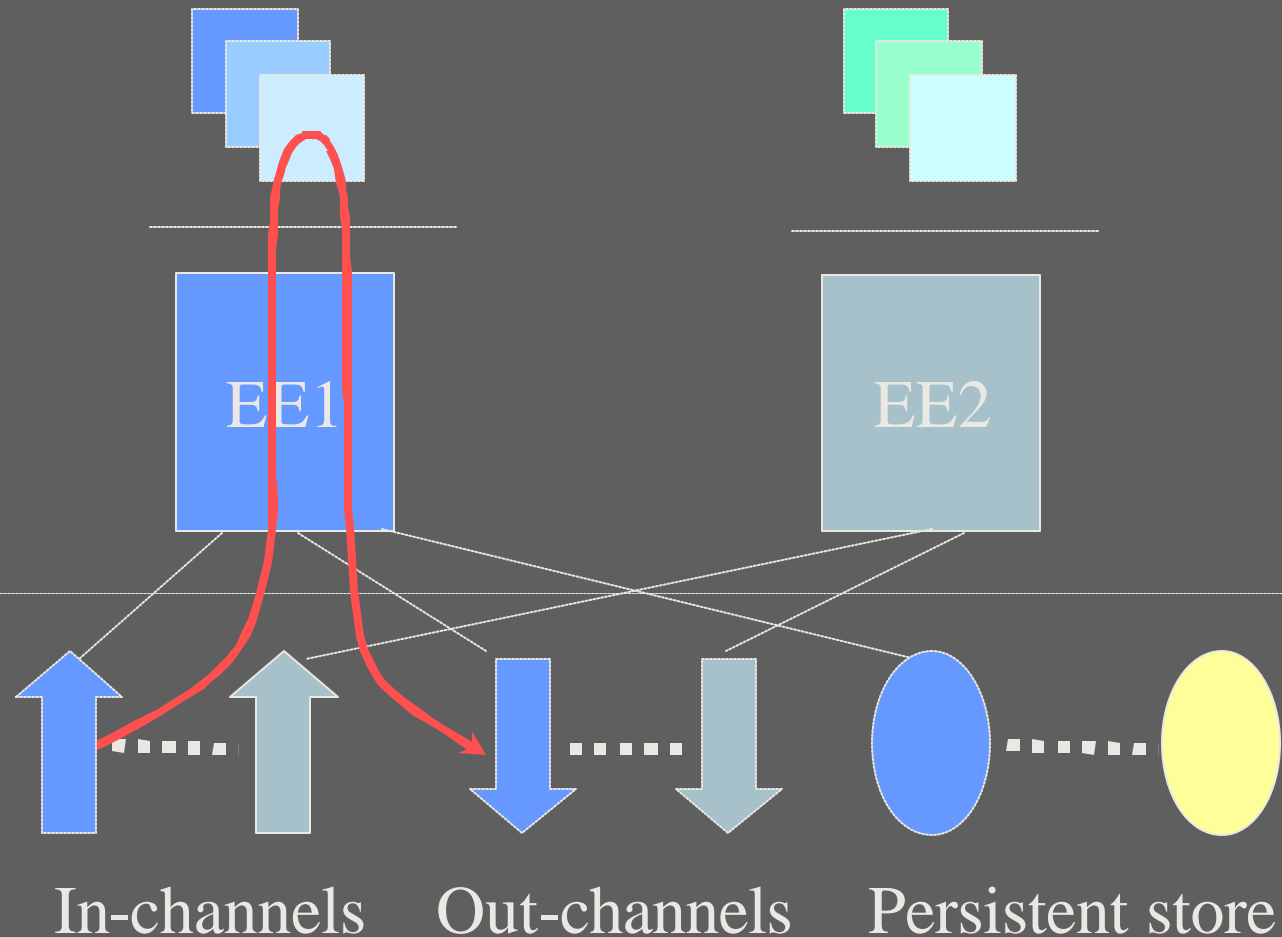

Active Networks Node Architecture

--- from S. Murphy's slides

Active Applications

Execution Environments

NodeOS

Security Requirements

- ⇒ Need to protect
 - End users, Active Node, EE, Active Code/Domain
- ⇒ End User's security concerns
 - authenticity, integrity and confidentiality
- ⇒ Active Node/EE's security concerns
 - authorization of use of its services and resources
 - integrity and confidentiality of its own state
- ⇒ Active Code's security concerns
 - access to its services and sharable persistent states

Trust Model --- End User Viewpoint

- ➔ Would rather not trust active nodes, EEs and other active codes
- ➔ So, End-End Cryptographic protections
 - Protect its own data from active node and EE
 - But limit the network services in active node
- ➔ Expected Features
 - Enable end users to choose trusted nodes/EEs
 - Avoid transmitting the packet to untrusted nodes/EEs

Trust Model --- Node Viewpoint

- ⇒ Would rather not trust EEs, active codes, arriving packets
- ⇒ Control over the allocation of resources and privileges to an EE's domain
- ⇒ Balance the trust it holds in an EE
- ⇒ Control the threat from active code
- ⇒ countering clogging attacks from arriving packets is another research area.

Trust Model --- EE Viewpoint

- ⇒ Would rather not trust active codes and arriving packets
- ⇒ Control the threat from active codes
- ⇒ Rely on the node to enforce the EE's policy governing acceptance of arriving packets

Trust Model --- Active Code Viewpoint

- ⇒ Would rather not trust Active node, EEs and other active codes
- ⇒ Active code must trust the nodes and EE's on/in which it executes
- ⇒ Avoid those it does not trust
- ⇒ Enforce its policy to avoid potential attacks from other active codes

Protection Techniques

⇒ Two Approaches

■ Language based

- Limit the possible actions of programs
- Low cost technique with a large payoff

■ Authorization based

- Associate a principal with each request for an action
- Enforce a policy that states which principals are permitted to perform which actions

Authentication Challenges

- ⇒ Identification of the principal itself in active networks
 - ▣ Multiple and varying principal identities or attributes
- ⇒ Choice of an authentication mechanism
 - ▣ Hop-Hop protections
 - ▣ Symmetric/Asymmetric techniques

SANTS

- ⇒ Security ANTS
- ⇒ Prototype a secure active network
 - ▣ Authorization enforcement
 - nodes, EE's and active code
 - ▣ Integrity protection
 - packets
 - ▣ Distributed authentication mechanism
 - Retrieval of identities and attributes
 - Dynamic assignment of attributes

Components

➔ Authentication

- X.509v3 certificates
- DNSSEC
- Java Crypto API
- KeyNote policy system

➔ Authorization

- Java 2 security features, class loader
- A separation between EE and Node Classes
- A shared data capability, Bulletin Board

Authentication

⇒ Hop-Hop

- ▣ HMAC-SHA1 integrity protection

⇒ End-End

- ▣ Digital signature for authentication and integrity protection

Authentication Issues

General Crypto Protected Packet

SANTS Protected Packet

SANTS Authentication

- ⇒ Strong End-End Authentication
 - ▣ Digital Signatures
 - ▣ Protection applies to static areas only
- ⇒ Hop-Hop Integrity
 - ▣ HMAC-SHA1
 - ▣ Protection Applies to entire packet
- ⇒ Distributed Security Infrastructure
 - ▣ X.509 Certificates stored in DNS CERT records
 - ▣ Access uses DNSSEC

SANTS Authorization

- ➔ Authorization Control at the NodeOS Level
 - ▣ Policy Manager in the NodeOS
 - ▣ Policy manager exposed
 - To EE
 - To Active Packet
- ➔ Authorization Based on Security Attributes
 - ▣ Carried in X.509 Certificates

Bulletin Board

- ⇒ Active packet travel through the network encountering different administration with their own policies.
- ⇒ EE provides a Bulletin Board shared data service to incoming active code.

Security Architecture

⇒ Includes:

- ▣ Naming
- ▣ Packet Format
- ▣ Policy Language
- ▣ Security Support System
- ▣ Enforcement Architecture

Security Architecture

- ⇒ Components should be placed in NodeOS
- ⇒ Domain creation NodeOS call must include an authentication policy and an access control policy.

Security Processing in NodeOS

- ➔ Receive packet
- ➔ Verify hop-hop integrity
- ➔ Assign packet to existing domain
- ➔ Extract credential list
- ➔ Check credentials authenticity according to authentication policy for the domain
- ➔ Check credentials against access control policy for domain
- ➔ Deliver entire packet to the domain, including the credentials, authentication protection fields, etc

Security processing in the EE

- ⇒ Receive a packet including credentials
- ⇒ Create a sub-domain, providing
 - ▣ security context parameters
 - ▣ access control and authentication policies
- ⇒ Modify
 - ▣ access control policy,
 - ▣ authentication policy
 - ▣ security context
- ⇒ Add or remove cryptographic protections to user data

Conclusion

- ⇒ SANTS does provide strong security
 - ▣ Fine Grained Authorization
 - ▣ Strong End-End Authentication
 - ▣ Dynamic Policies

- ⇒ Too Complicated, is it worthy to apply?
