Overview

- ↓ Understanding of the riverine dissolved organic matter (DOM) is important however little is known about this material in a molecular level.
- ↓ Riverine DOM is a major source of carbon flow to the oceans and plays an important role in the global cycle of carbon.

A riddle in a global carbon cycle

(units: Gt)

Adapted from Houghton *et al.* Climate change 1994 (1995), Cambridge Press, New York

* Meyers-Schuttle & Hedges, Nature (1986), 321, 61-63

- 0.3 Gt of carbon is large enough to sustain the turnover of the entire ocean
- However, a little resemblance was found between two carbon pools.
- Low amount of lignin phenol (terrestrial bio-marker) exists in oceanic DOC pool.*
- $\delta^{13}\text{C}$ isotope signatures are different.

Isolation of DOM from natural river water samples

How to isolate the DOM?

		
XAD extraction	Established method	Final elution include salt – dialysis necessary Large volume of chemical
Ultrafiltration	Fractionation possible	Large amount of sample Requires instrument
Freezedrying	Not-selective	Takes a long time Concentrate salts too

How to isolate DOM from river water?

↓ Disk type C₁₈ solid phase extraction

Benefits

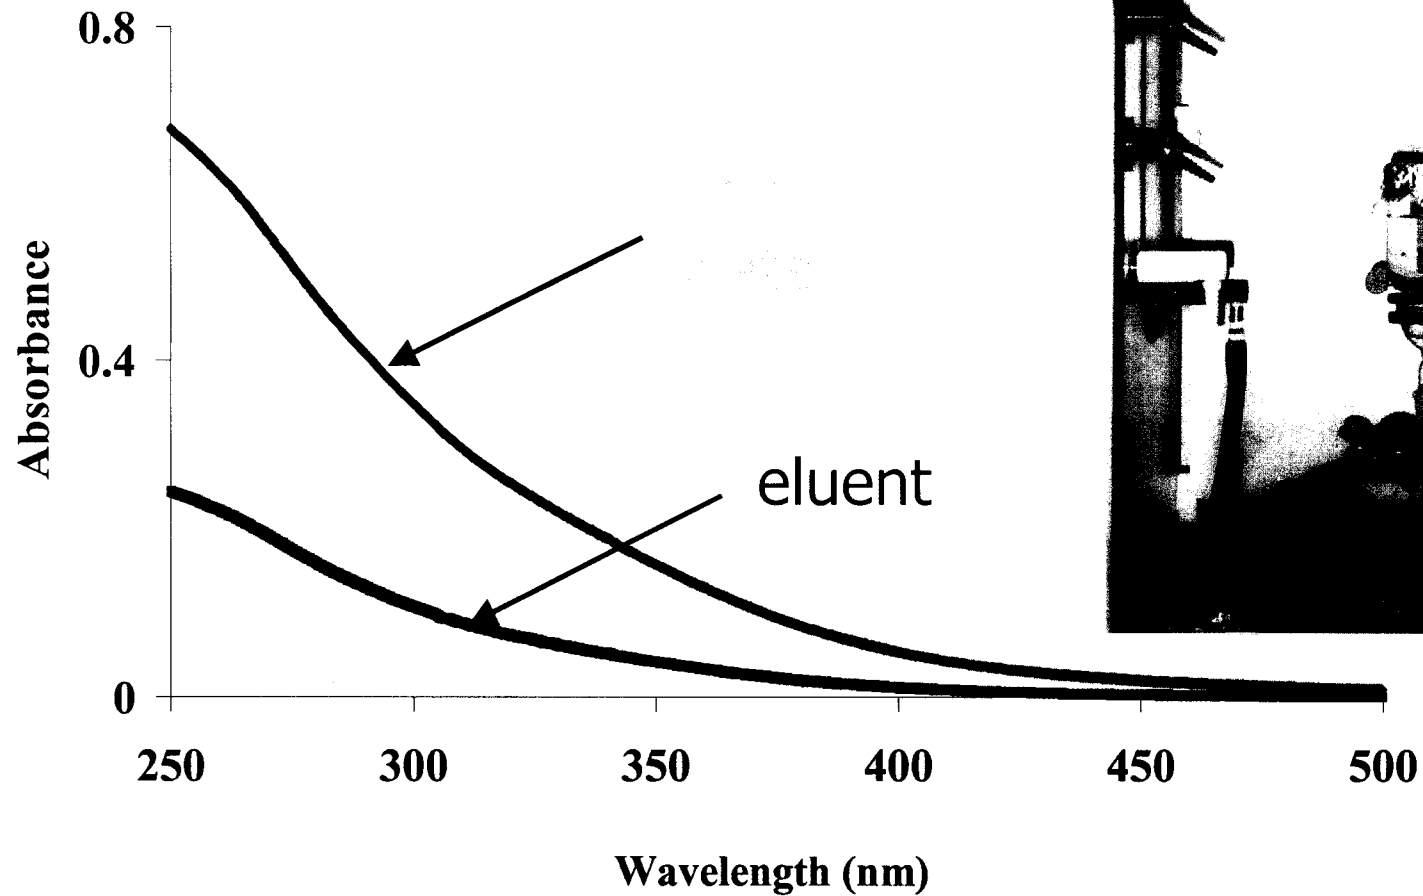

1. Faster extraction
2. Simple experiment setup
3. easily handle small amount of sample

Questions to be answered

1. Retention rate?
2. Does collected sample reflect DOM in river?

Retention rate?

Retention rate of ~ 70 %

Does final eluent reflect the DOM in river?

DOM acquired
by freeze drying

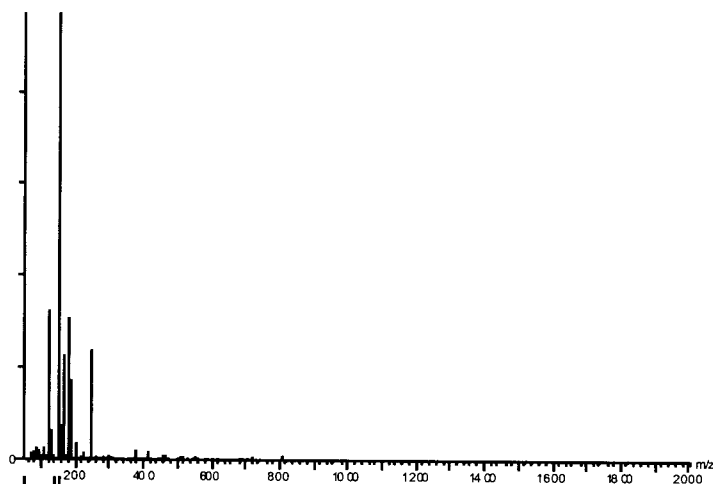

DOM acquired

Sample by freeze-drying

Sample by C₁₈ SDE

(1) aromatics; (2) sugars; aliphatic units bridging lignin aromatics; amino acids (α - β couplings); (3) methylene units adjacent to ethers, esters, and hydroxyls in aliphatic chains; amino acids (α - β - γ couplings); (4) methylene in aliphatic chains; and methyl units in amino acids and aliphatic chains.

Conclusion

- 1. DOM can be extracted with C₁₈ solid phase disk extraction in a shorter time with simple equipment.
- 2. Extracted DOM was successfully analyzed by high resolution ESI-MS resulting high resolution spectra.

Resolving power is very critical

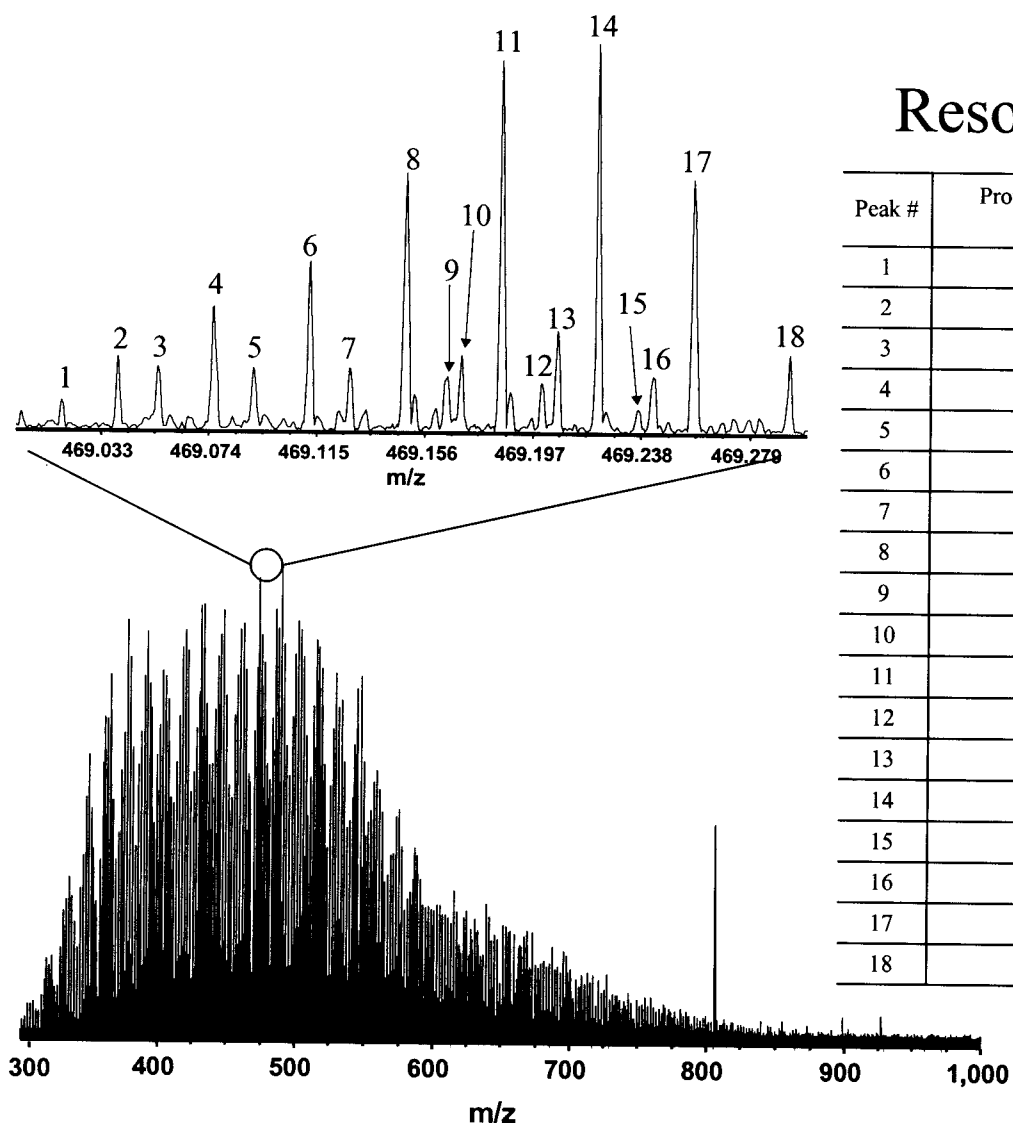

← Q-TOF analysis of DOM
Resolving power ~10,000

7 T FT-ICR analysis of DOM
Resolving power ~80,000

Ultra-high resolution spectrum of DOM

Resolving power $\sim 200,000$

Graphical-statistical method for the study of structure and reaction processes of coal

D. W. VAN KREVELEN, D.Sc., M.A.I.Ch.E.

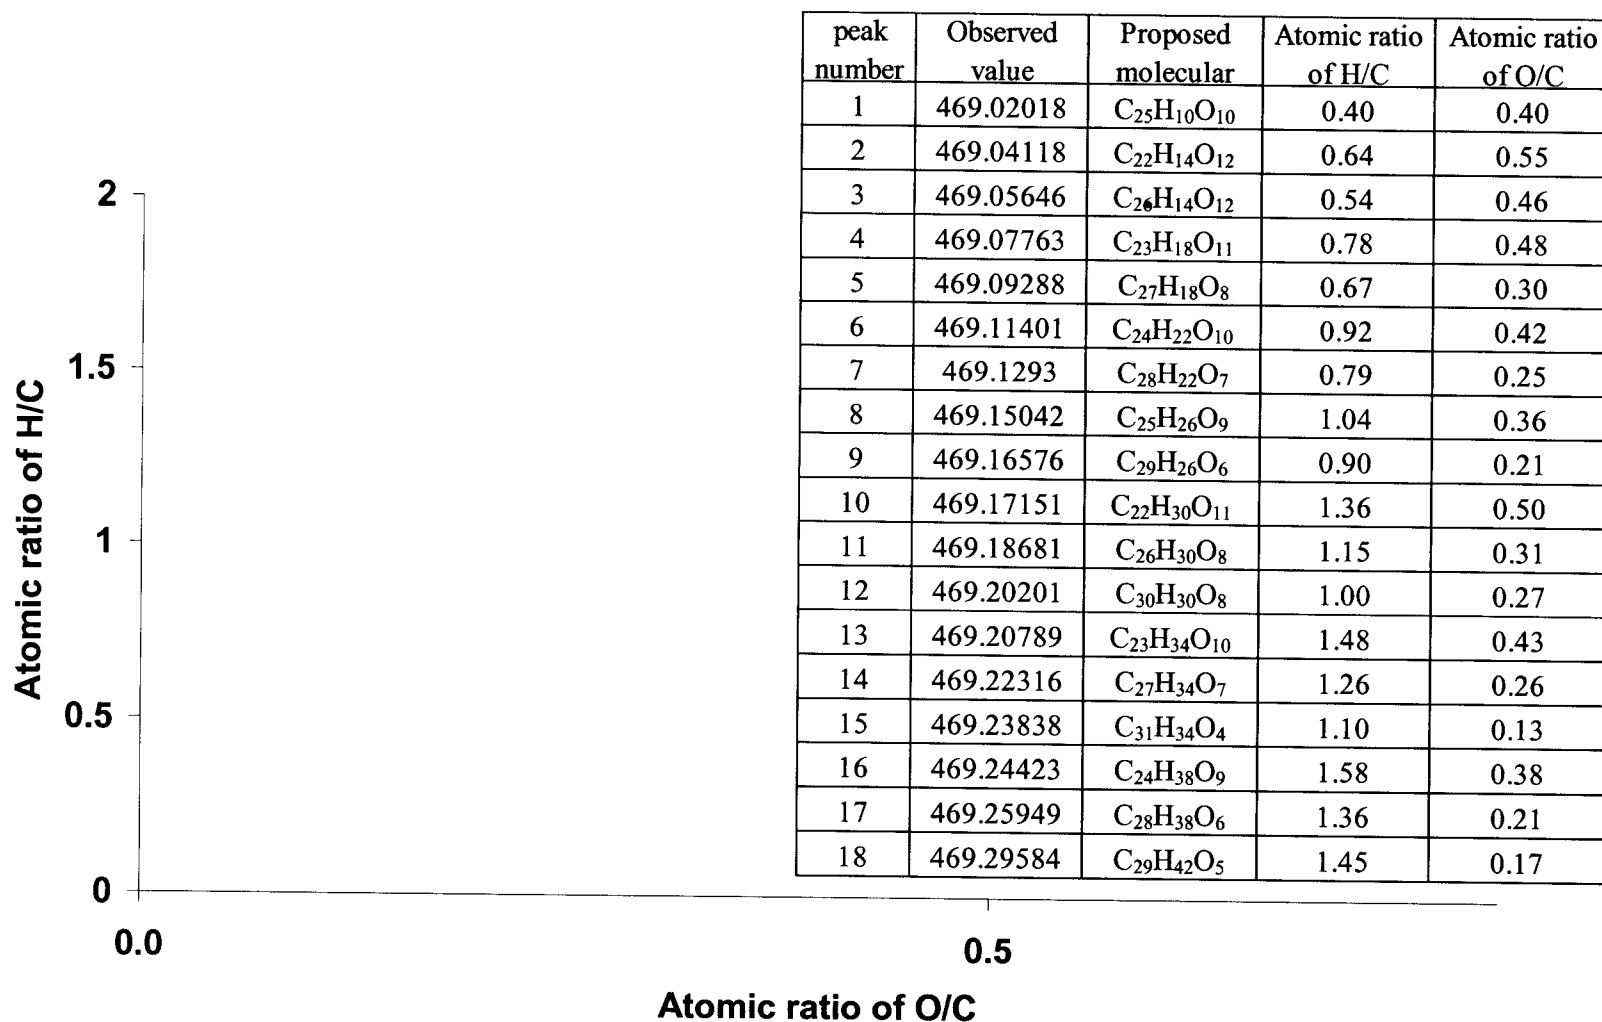

A graphical-statistical method is developed for the study of problems connected with structure and reaction processes of coal. In this method use is made of a diagram in which the atomic hydrogen-to-carbon ratio has been plotted versus the atomic oxygen-to-carbon ratio. This graphical method offers the advantage that the principal reactions such as decarboxylation, demethanation, dehydration, dehydrogenation, hydrogenation and oxidation in the aforementioned diagram can be represented by straight lines. Furthermore, an auxiliary diagram is used where the hydrogen-to-carbon ratio of hydrocarbons has been plotted as a function of the number of carbon atoms per molecule. From a combination of the two diagrams valuable information can be drawn as regards the structure of oxygen containing organic products e.g. high polymers, such as cellulose. These ideas are applied to the coalification series. The skeleton structure of lignin evolved in the literature proves to be in conformity with the results of the graphical statistical method. The conversion of lignite to bituminous coal is found to be based on a decarboxylation: the conversion from high rank bituminous coal to anthracite is a reaction process in which methane is removed almost exclusively in the transition from low rank to high rank bituminous coal a decarboxylation as well as a demethanation and a dehydration occur. The stoichiometry of the coalification is expressed in formulae. A correlation is made between the coalification of various vegetable components and the rank of coal in which the product formed cannot be distinguished from vitrain. Finally the formation process of fusain is studied in more detail and this leads to the construction of a fusinization band by the side of the coal band (=vitrinization band). The principal reaction processes of coal, namely carbonization, hydroconversion, solvent extraction, hydrogenolysis and oxidation, are investigated by a graphical-statistical method. It proves that both in carbonization and in oxidation with gaseous oxygen all coalification products show a tendency to yield a uniform final product; in the carbonization this product has the composition $(C_8H_2O_{0.16})_x$, in the case of oxidation the composition is $(C_8H_2O_3)_x$. Further carbonization results in a graphitization, while an oxidation beyond the above composition gives a complete conversion to carbon dioxide and water. Thermal decomposition in the presence of water vapour under pressure must be based on a reaction mechanism which is closely related with the coalification. In hydrogenation the character of the final products depends both on the character of the starting material and on the conditions under which the hydrogenation is carried out. In oxidation with nitric acid, two stages can be distinguished: in the first stage hydrogen is removed while oxygen is absorbed, in the second stage both hydrogen and oxygen are absorbed and this in the approximate proportion of 1:1. Solvent extraction of coal shows that coal is not a homogeneous macromolecule: there is either a differentiation in molecular size or such a configuration that fragments of a relatively low molecular weight are split off rather easily.

Existence of hydrogen deficient molecules in natural river water samples – an implication for black carbon and black carbon cycle

Black carbon (BC)

- The black carbon (BC) is byproduct of incomplete combustion processes.
- BC has been shown to have discernable influence on biogeochemical cycles, climate change, human health, fertility of soils, and bioavailability of toxins.
- BC is generally accepted to be refractory.

Rio Negro

THE AMAZON

- The Rio Negro is one of the three major tributaries of the Amazon river (accounting for 30 % of Amazon river discharge).
- The Amazon river is the largest river in the world accounting for 20 % of fresh water discharge into the ocean

BC

IS BC soluble in water ?

- Oxidation is an important step for microbial degradation of poly-aromatic carbon¹.

- Microbial decomposition of low rank coal has been reported. However, it is generally known that the degradation process is slow.

1. A. Tschech, *Forum Mikrobiol.* **12**, 251-264 (1989).

Is BC degradable?

.05-0.26 Gt/year of BC
from biomass burning

Global carbon budget
 Terrestrial: 3,060 Gt C
 Ocean: 40,000 Gt C
 + Atmosphere: 750 Gt C

 Total: 43,810 Gt C

$43810 / 0.05 = 876,200$ years
 $43810 / 0.26 = 168,500$ years

Goldberg

Goldberg, Black carbon in the environment (1985) Wiley, New York

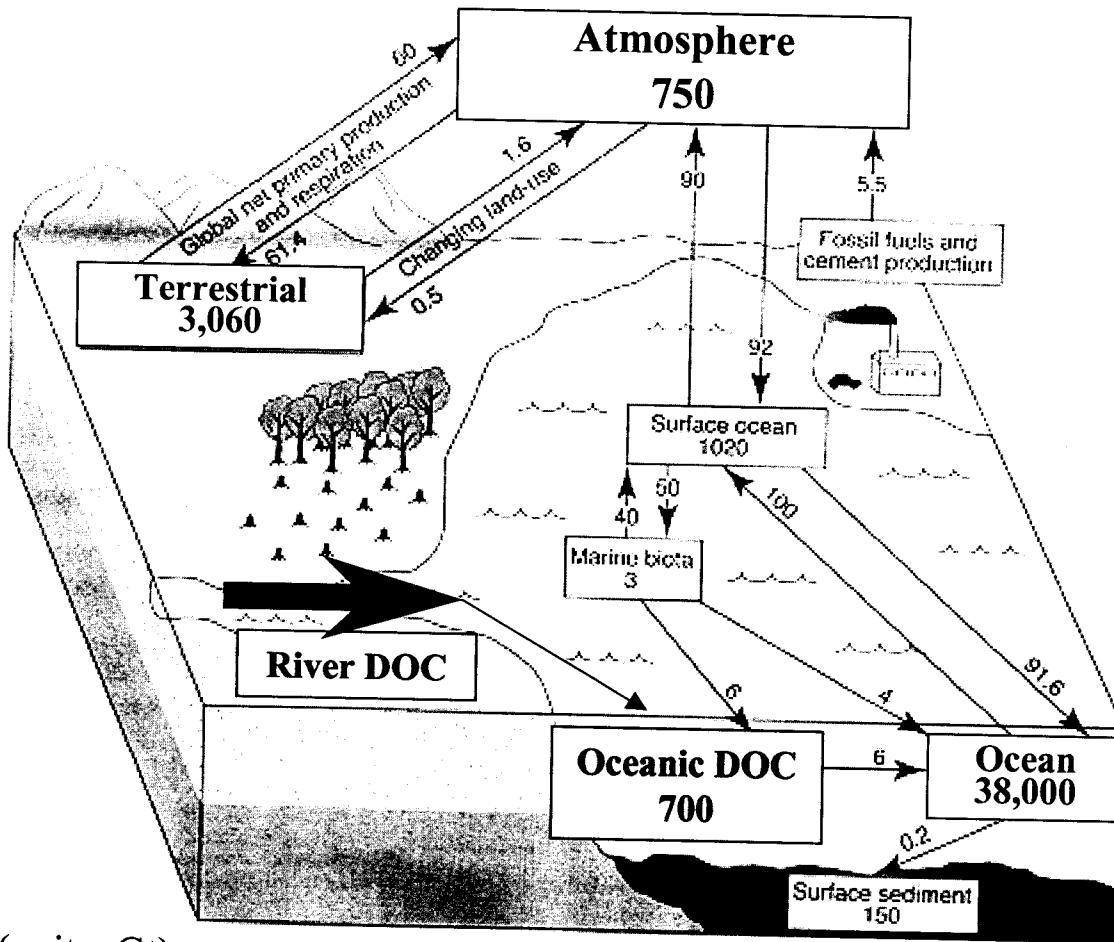

A hypothesis - global black carbon cycle

1. BC is a source of old carbon in the river DOM
2. BC flows into the ocean and is included in oceanic DOM
3. BC flows into the deep ocean
4. BC in DOM is included into particulate organic matter (POM)
5. BC in POM is deposited to ocean sediment

The hypothesis can partly solve the riddle in a global carbon cycle

Selective inclusion of refractory component of river DOC into oceanic DOC pool

(units: Gt)

- “Significant amount of carbon transferred from terrestrial systems to the deep ocean or marine sediments would help balance models of the global carbon cycle.”

Schlesinger and Melack, *Tellus* (1981), 33, 172-187
