On the Conditioning of Random Block Subdictionaries

Waheed U. Bajwa,* Robert Calderbank, and Marco F. Duarte*

Technical Report TR-2010-06
Department of Computer Science
Duke University
September 22, 2010

1 Introduction

The use of sparsity as a prior for efficient signal acquisition and processing has become prevalent in the last decade. In particular, compressed sensing (CS) [3, 4] uses sparsity to reduce the number of samples.measurements needed to acquire a signal. The performance of CS hinges on certain properties of the measurement matrix that maps the input signal to the obtained measurements. Early results in CS focused on deterministic conditions on the measurement matrix for the case of arbitrary (deterministic) signals. However, the conditions are either difficult to verify or provide highly pessimistic bounds on recovery performance.

Recent results by Tropp [11] have focused on the performance of measurement matrices for sparse signals under a probabilistic signal model where the support is drawn at random from a uniform distribution over all sparse supports of a given size. The result exploits the fact that the product of a matrix with a sparse signal is essentially controlled by the subdictionary corresponding to the signal support. In this case, recovery performance is tied to the coherence and spectral norm of the matrix through the calculation of the expected spectral norm of randomly selected subdictionaries of the matrix.

*Equal contribution. WUB is with the Department of Electrical and Computer Engineering, RC is with the Departments of Computer Science, Electrical and Computer Engineering, and Mathematics, and MFD is with the Department of Computer Science at Duke University, Durham, NC 27708. RC and MFD are also with the Program in Applied and Computational Mathematics, Princeton University, Princeton, NJ 08544. This work was supported by grants ONR N00014-08-1-1110 and AFOSR FA9550-09-1-0422, FA9550-09-1-0643, and FA9550-05-0443. MFD was also supported by NSF Supplemental Funding DMS-0439872 to UCLA-IPAM, P.I. R. Caflisch.
In this report, we adapt these results to applications where the signal exhibits block (or group) sparsity, rather than simple sparsity. That is, the block-sparse signal has support that is drawn uniformly at random from all block-sparse supports containing a given number of blocks. In block sparsity, the nonzero coefficients of the sparse signal are grouped together as intervals in the signal coefficient vector. The block sparsity model is popular for multiband signals, fusion frames, and signal ensemble applications [1, 2, 5, 6, 8]. Thus, our results focus on random block subdictionaries, where the columns selected from the measurement matrix are grouped together into intervals. The results in this paper can also have implications on the performance of block-sparse signal recovery under the random block-sparse support model.

This report is organized as follows. Section 2 sets up notation and presents our main theorem. Section 3 provides necessary lemmas, and Section 4 gives the proof of our main theorem.

2 Notation and Main Result

The measurement matrix (or dictionary) is \( \Phi = [\Phi_1 \ \Phi_2 \ \ldots \ \Phi_p] \), where each block \( \Phi_i = [\phi_{i,1} \ \ldots \ \phi_{i,m}] \) is an \( n \times m \) matrix. The dictionary has coherence

\[
\mu := \max_{(i,j) \neq (k,l)} \|\phi_{i,j}, \phi_{k,l}\|_2
\]

and each of its columns \( \phi_{i,j} \) has unit norm. We define random variables \( \delta_1, \ldots, \delta_p \) that are independent and identically distributed (i.i.d.) Bernoulli with parameter \( \delta := k/p \), and form a block subdictionary \( X = [\Phi_i : \delta_i = 1] \). The hollow Gram matrix for \( X \) is \( A := X^H X - I \), where \( I \) denotes the identity matrix of appropriate size. To calculate the spectral norm of \( A \), we use a masking matrix \( R = S \otimes I_m \), where \( S = \text{diag}(\delta_1, \ldots, \delta_p) \) is a random matrix and \( \otimes \) denotes the standard Kronecker product. We then have \( \|A\|_2 = \|RGR\|_2 \) with \( G := \Phi^H \Phi - I \). We denote \( \mathbb{E}_q X := [\mathbb{E}|X|^q]^{1/q} \). We also define the block coherence\(^1\)

\[
\mu_B = \max_{1 \leq i,j \leq p} \|\Phi_i^H \Phi_j - 1_{\{i=j\}} I\|_2.
\]

Finally, we denote \( T \subseteq \{1, \ldots, p\} \) to be a subset of the block index set, with \( T^C := \{1, \ldots, p\} \setminus T \). Using this notation, the main result of this report can be stated as follows.

**Theorem 1.** For \( q = 2 \log(pm) \), we have the bound

\[
\mathbb{E}_q \|RGR\|_2 \leq 20\mu_B \log(pm) + 9\sqrt{\delta \log(pm)}(1 + (m - 1)\mu)\|\Phi\|_2 + \delta\|\Phi\|_2^2.
\]

\(^1\)We recently became aware of [5], which also introduces the term "block coherence" in the context of recovery of block-sparse signals, defined as \( \max_{i \neq j} \|\Phi_i^H \Phi_j\|_2 \).
The proof of the theorem uses many lemmas and tools, following the ideas of the proof in [11]. To begin, we denote the matrix $G$ in block-diagonal fashion:

$$
G = \begin{bmatrix}
G_{1,1} & G_{1,2} & \cdots & G_{1,p} \\
G_{2,1} & G_{2,2} & \cdots & G_{2,p} \\
\vdots & \vdots & \ddots & \vdots \\
G_{p,1} & G_{p,2} & \cdots & G_{p,p}
\end{bmatrix}
$$

where $G_{i,j} = \Phi_i^H \Phi_j - 1_{i=j} I$ for $1 \leq i, j \leq p$. We then split $G = H + D$, where $D$ contains the diagonal blocks $G_{i,i}$, and $H$ contains only the non-diagonal blocks. We also define the following “norms” for block matrices:

- when we group only the columns, we define $\|G\|_{B,1} := \max_{1 \leq i \leq p} \|G_i\|_2$;
- when we group both columns and rows, we define $\|G\|_{B,2} := \max_{1 \leq i,j \leq p} \|G_{i,j}\|_2$.

Finally, we will make use of the following standard inequalities:

- Cauchy-Schwarz Inequality: $|\mathbb{E}(XY)|^2 \leq \mathbb{E}(X^2)\mathbb{E}(Y^2)$.
- Hölder’s Inequality: $\|fg\|_1 \leq \|f\|_p \|g\|_q$, $1 \leq p, q \leq \infty$ and $1/p + 1/q = 1$.
- Jensen’s Inequality for a convex function $f$: $f(\mathbb{E}X) \leq \mathbb{E}f(X)$.
- Scalar Khintchine Inequality: Let $\{a_i\}$ be a finite sequence of complex numbers and $\{\epsilon_i\}$ be a Rademacher (random $\pm 1$ binary) sequence. For each $q \geq 0$, we have

$$
\mathbb{E}_q \left| \sum_i \epsilon_i a_i \right| \leq C_q \left( \sum_i |a_i|^2 \right)^{1/2},
$$

where $C_q \leq 2^{1/4} \sqrt{q/e}$.

- Noncommutative Khintchine Inequality [12]: Let $\{X_i\}$ be a finite sequence of matrices of the same size and $\{\epsilon_i\}$ be a Rademacher sequence. For each $q \geq 2$,

$$
\mathbb{E}_q \left\| \sum_j \epsilon_j X_j \right\|_{S_q} \leq W_q \max \left\{ \left\| \left( \sum_j X_j X_j^H \right)^{1/2} \right\|_{S_q}, \left\| \left( \sum_j X_j^H X_j \right)^{1/2} \right\|_{S_q} \right\},
$$

where $\|X\|_{S_q} = \|\sigma(X)\|_q$ denotes the Schatten $q$-norm for a matrix (equal to the $\ell_q$-norm of the vector containing its singular values) and $W_q \leq 2^{-1/4} \sqrt{\pi q/e}$.
3 Lemmata

We use the following lemmas in our proof of Theorem 1. The first two lemmas are used to prove later ones.

**Lemma 1.** Let $X = [X_1 \ldots X_p]$ be a block matrix and $D_X$ be its block diagonalization, i.e., a block-diagonal matrix $D_X = \text{diag}(X_i)_{i=1}^{p}$ containing the square matrices $X_i$ in its diagonal, with all other elements being equal to zero. Then, we have

$$
\|D_X\|_2 \leq \|X\|_{B,1}.
$$

**Proof.** For a vector $a$ of appropriate length, we evaluate the ratio $\frac{\|D_Xa\|^2}{\|a\|^2}$. We partition $a = [a_1 \ a_2 \ldots \ a_p]$ into pieces matching the number of columns of the blocks $X_i$, $1 \leq i \leq p$. Then, we will have

$$
\frac{\|D_Xa\|^2}{\|a\|^2} = \frac{\sum_{i=1}^{p} \|X_ia_i\|^2}{\sum_{i=1}^{p} \|a_i\|^2} \leq \frac{\sum_{i=1}^{p} \|X_i\|^2 \|a_i\|^2}{\sum_{i=1}^{p} \|a_i\|^2} \leq \max_{1 \leq i \leq p} \|X_i\|^2.
$$

Thus, the spectral norm obeys

$$
\|D_X\|_2 = \max_a \frac{\|D_Xa\|^2}{\|a\|^2} \leq \max_{1 \leq i \leq p} \|X_i\|_2 = \|X\|_{B,1}.
$$

The next lemma is adapted from [9].

**Lemma 2.** Let $X = [X_1 \ X_2 \ldots \ X_p]$ be a block matrix where each block $X_i$ has $m$ columns. For any $q \geq 2 \log(pm)$, we have

$$
\| \sum_{i=1}^{p} \epsilon_i X_i X_i^H \|_2 \leq 1.5 \sqrt{q} \|X\|_{B,1} \|X\|_2,
$$

where $\{\epsilon_i\}$ is a Rademacher sequence.

**Proof.** We start by bounding the spectral norm by the Schatten $q$-norm:

$$
E := \mathbb{E}_q \left\| \sum_{i=1}^{p} \epsilon_i X_i X_i^H \right\|_2 \leq \mathbb{E}_q \left\| \sum_{i=1}^{p} \epsilon_i X_i X_i^H \right\|_{S_q}.
$$

Now use the noncommutative Khintchine inequality (noting that the two terms in the inequality’s max are equal) to get

$$
E \leq W_q \left\| \left( \sum_{i=1}^{p} X_i X_i^H X_i X_i^H \right)^{1/2} \right\|_{S_q}.
$$
We can bound the Schatten $q$-norm by the spectral norm by paying a multiplicative penalty of $(pm)^{1/q}$, where $pm$ is the maximum rank of the matrix sum. By the hypothesis, this penalty does not exceed $\sqrt{e}$.

\[
E \leq W_q \sqrt{e} \left\| \sum_{i=1}^{p} X_i X_i^H X_i X_i^H \right\|_2^{1/2} \\
\leq W_q \sqrt{e} \left\| \sum_{i=1}^{p} X_i X_i^H X_i X_i^H \right\|_2^{1/2}
\]

We note that the sum term is a quadratic form that can be expressed in terms of $X$ and its block diagonalization, as follows:

\[
E \leq W_q \sqrt{e} \left\| XD_X^HD_X X^H \right\|_2^{1/2} \leq W_q \sqrt{e} \left\| D_X X^H \right\|_2 \\
\leq W_q \sqrt{e} \left\| X \right\|_{B,1} \left\| X \right\|_2,
\]

where the last step used Lemma 1. Now replace $W_q \leq 2^{-1/4} \sqrt{\pi q/e}$ to complete the proof.

The next lemma is adapted from [11].

**Lemma 3.** Let $H$ be a a Hermitian matrix with zero block diagonal. Then $E_q\|RHR\|_2 \leq 2E_q\|RHR'\|_2$, where $R' = S' \otimes I_m$ with $S'$ denoting an independent realization of the random matrix $S$.

**Proof.** We establish the result for $q = 1$ for simplicity. Denote $H_{i,j} = \Phi_i^H \Phi_j - 1_{(i=j)} I$ for $1 \leq i, j \leq p$. Further, denote $\bar{H}_{i,j}$ as the masking of the matrix $H$ that preserves only the subblock $H_{i,j}$.

\[
E_q\|RHR\|_2 = E_q \left\| \sum_{1 \leq i < j \leq p} \delta_i \delta_j (\bar{H}_{i,j} + \bar{H}_{j,i}) \right\|_2.
\]

Let $\eta_i$ be i.i.d. Bernoulli random variables with parameter $1/2$. Here, we use Jensen’s inequality on the new random variable $\eta = \{\eta_i\}_{1 \leq i \leq p}$: we define $M_{i,j}(\eta) = \eta_i(1 - \eta_j) + \eta_j(1 - \eta_i)$, and note that $E_\eta M_{i,j}(\eta) = 1/2$ for all $i, j$. We also define the function

\[
f(M_{i,j}(\eta)) = E_\delta \left\| \sum_{1 \leq i < j \leq p} 2\delta_i \delta_j M_{i,j}(\eta)(\bar{H}_{i,j} + \bar{H}_{j,i}) \right\|_2.
\]

Thus, by applying Jensen’s inequality to $f(\cdot)$, we obtain

\[
E q\|RHR\|_2 \leq 2E_q E_\delta \left\| \sum_{1 \leq i < j \leq p} [\eta_i(1 - \eta_j) + \eta_j(1 - \eta_i)] \delta_i \delta_j (\bar{H}_{i,j} + \bar{H}_{j,i}) \right\|_2.
\]
There is a 0-1 vector $\eta^*$ for which the expression exceeds its expectation over $\eta$. Let $T = \{ i : \eta^*_i = 1 \}$.

\[
\mathbb{E}\|RHR\|_2 \leq 2\mathbb{E}_\delta \sum_{i \in T, j \in T^C} \delta_i \delta_j (\bar{H}_{i,j} + \bar{H}_{j,i}) \leq 2\mathbb{E}_\delta \sum_{i \in T, j \in T^C} \delta_i \delta_j \bar{H}_{i,j}
\]

where $\{\delta'_i\}$ is an independent realization of the sequence $\{\delta_i\}$. The first equality follows from a standard identity for block counter-diagonal Hermitian matrices. Now the norm of a submatrix does not exceed the norm of the matrix, so we re-introduce the missing blocks to complete the argument:

\[
\mathbb{E}\|RHR\|_2 \leq 2\mathbb{E}_\delta \sum_{1 \leq i, j \leq p, i \neq j} \delta_i \delta'_j \bar{H}_{i,j} \leq 2\mathbb{E}_\delta\|RHR'\|_2.
\]

The next lemma is adapted from [10, 12].

**Lemma 4.** Let $B = [B_1 \ldots B_p]$ be a matrix with $p$ column blocks, and suppose $q \geq 2 \log(pm) \geq 2$. Then

\[
\mathbb{E}_q\|BR\|_2 \leq 3\sqrt{q}\mathbb{E}_q\|BR\|_{B,1} + \sqrt{\delta}\|B\|_2.
\]

**Proof.** We denote $E := \mathbb{E}_q\|BR\|_2$, and have

\[
E^2 = \mathbb{E}_{q/2}\|BRB^H\|_2 = \mathbb{E}_{q/2} \left\| \sum_{1 \leq i \leq p} \delta_i B_i B_i^H \right\|_2
\]

\[
\leq \mathbb{E}_{q/2} \left\| \sum_{1 \leq i \leq p} (\delta_i - \delta) B_i B_i^H \right\|_2 + \delta \left\| \sum_{1 \leq i \leq p} B_i B_i^H \right\|_2
\]

Here we replace $\delta = \mathbb{E}\delta'$, with $\{\delta'_i\}$ denoting an independent copy of the sequence $\{\delta_i\}$. We then take the expectation out of the norm with Jensen’s inequality to get

\[
E^2 \leq \mathbb{E}_{q/2} \left\| \sum_{1 \leq i \leq p} (\delta_i - \delta'_i) B_i B_i^H \right\|_2 + \delta\|BB^H\|_2.
\]
We symmetrize the distribution by introducing a Rademacher sequence \( \{\epsilon_i\} \), noticing that the expectation does not change due to the symmetry of the random variables \( \delta_i - \delta'_i \):

\[
E^2 \leq \mathbb{E}_{q/2} \left\| \sum_{1 \leq i \leq p} \epsilon_i (\delta_i - \delta'_i) B_i B_i^H \right\|_2^2 + \delta \|B\|_2^2.
\]

We apply the triangle inequality to separate \( \delta_i \) and \( \delta'_i \), and by noticing that they have the same distribution, we obtain

\[
E^2 \leq 2 \mathbb{E}_{q/2} \left\| \sum_{1 \leq i \leq p} \epsilon_i \delta_i B_i B_i^H \right\|_2^2 + \delta \|B\|_2^2.
\]

Writing \( \Omega = \{i : \delta_i = 1\} \), we see that

\[
E^2 \leq 2 \mathbb{E}_{q/2, \Omega} \left( \mathbb{E}_{q/2, \epsilon} \left\| \sum_{i \in \Omega} \epsilon_i B_i B_i^H \right\|_2 \right) + \delta \|B\|_2^2.
\]

Here we have split the expectation on the random variables \( \Omega \) and \( \{\epsilon_j\} \). Now we use Lemma 2 on the term in parentheses to get

\[
E^2 \leq 3 \sqrt{q} \mathbb{E}_{q/2, \Omega} (\|BR\|_{B,1} \|BR\|_2) + \delta \|B\|_2^2.
\]

Using the Cauchy-Schwarz inequality, we get

\[
E^2 \leq 3 \sqrt{q} \mathbb{E}_q \|BR\|_{B,1} \mathbb{E}_q \|BR\|_2 + \delta \|B\|_2^2.
\]

This inequality takes the form \( E^2 \leq b E + c \). We bound \( E \) by the largest solution of this quadratic form:

\[
E \leq \frac{b + \sqrt{b^2 + 4c}}{2} \leq b + \sqrt{c},
\]

proving the lemma.

The last lemma is adapted from [12].

**Lemma 5.** Let

\[
B = [B_1 \; B_2 \; \ldots \; B_p] = \begin{bmatrix}
B_{1,1} & B_{1,2} & \ldots & B_{1,p} \\
B_{2,1} & B_{2,2} & \ldots & B_{2,p} \\
\vdots & \vdots & \ddots & \vdots \\
B_{p,1} & B_{p,2} & \ldots & B_{p,p}
\end{bmatrix}
\]

be a block matrix, where each block \( B_{i,j} \) has size \( m \times m \). Assume \( q \geq 2 \log p \). Then we have

\[
\mathbb{E}_q \|RB\|_{B,1} \leq 2^{1.5} \sqrt{q} \|B\|_{B,2} + \sqrt{3} \|B\|_{B,1}.
\]
Proof. We begin by seeing that

\[ E^2 := \left( \mathbb{E}_q \|RB\|_{B,1} \right)^2 = \mathbb{E}_q \left( \max_{1 \leq j \leq p} \|RB_j\|_2^2 \right) = \mathbb{E}_{q/2} \left( \max_{1 \leq j \leq p} \sum_{i=1}^p \delta_i \|B_{i,j}\|_2^2 \right) \]

In the sequel, we abbreviate \( t = q/2 \) and \( y_{i,j} = \|B_{i,j}\|_2^2 \). We continue by using the same technique as in the proof of Lemma 4: we split a term for the mean value of the sequence \( \{\delta_i\} \), then replace the term by \( \mathbb{E}_t \delta_{i,j} \), then exploit symmetrization by introducing a Rademacher sequence \( \{\epsilon_i\} \), and then finish by merging the two terms due to their identical distributions:

\[ E^2 \leq \mathbb{E}_t \left( \max_{1 \leq j \leq p} \sum_{i=1}^p (\delta_i - \delta) y_{i,j} \right) + \delta \max_{1 \leq j \leq p} \sum_{i=1}^p \|B_{i,j}\|_2^2 \]

\[ \leq \mathbb{E}_t \left( \max_{1 \leq j \leq p} \sum_{i=1}^p (\delta_i - \delta') y_{i,j} \right) + \delta \|B\|_{B,1}^2 \]

\[ = \mathbb{E}_t \left( \max_{1 \leq j \leq p} \sum_{i=1}^p \epsilon_i (\delta_i - \delta') y_{i,j} \right) + \delta \|B\|_{B,1}^2 \]

\[ \leq 2\mathbb{E}_t \left( \max_{1 \leq j \leq p} \sum_{i=1}^p \epsilon_i \delta y_{i,j} \right) + \delta \|B\|_{B,1}^2. \]

Now we bound the maximum by the sum and separate the expectations on the two sequences:

\[ E^2 \leq 2\mathbb{E}_{t,\delta} \left( \sum_{j=1}^p \left( \mathbb{E}_{t,\epsilon} \sum_{i=1}^p \epsilon_i \delta y_{i,j} \right) \right)^{1/t} + \delta \|B\|_{B,1}^2. \]

For the inner term, we can use the scalar Khintchine inequality to obtain

\[ E^2 \leq 2C_t \mathbb{E}_{t,\delta} \left( \sum_{j=1}^p \left( \sum_{i=1}^p \delta_i y_{i,j}^2 \right)^{t/2} \right)^{1/t} + \delta \|B\|_{B,1}^2. \]

We continue by bounding the outer sum by the maximum term:

\[ E^2 \leq 2C_t p^{1/t} \mathbb{E}_{t,\delta} \left( \max_{1 \leq j \leq p} \left( \sum_{i=1}^p \delta_i y_{i,j}^2 \right)^{t/2} \right)^{1/t} + \delta \|B\|_{B,1}^2. \]

Since \( t \geq \log p \), it holds that \( p^{1/t} \leq e \), which implies that \( 2C_t p^{1/t} \leq 4\sqrt{t} \). We now use Hölder’s inequality inside the sum term \( \delta_i y_{i,j}^2 = y_{i,j} \cdot \delta_i y_{i,j} \) with \( p = \infty \),
q = 1:

$$E^2 \leq 4\sqrt{t} \left( \max_{1 \leq i, j \leq p} y_{i,j} \right)^{1/2} \mathbb{E}_{i, \delta} \left( \max_{1 \leq j \leq p} \left( \sum_{i=1}^{p} \delta_i |y_{i,j}| \right)^{1/t} \right)^{1/t} + \delta \|B\|_{B,1}^2$$

$$\leq 4\sqrt{t} \left( \max_{1 \leq i, j \leq p} y_{i,j} \right)^{1/2} \mathbb{E}_{i, \delta} \left( \max_{1 \leq j \leq p} \left( \sum_{i=1}^{p} \delta_i |y_{i,j}| \right)^{1/2} \right)^{1/2} + \delta \|B\|_{B,1}^2.$$

Now we recall that $t = q/2$ and $y_{i,j} = \|B_{i,j}\|_2^2$, to get

$$E^2 \leq 2^{1.5} \sqrt{q} \max_{1 \leq i, j \leq p} \|B_{i,j}\|_2 \mathbb{E}_{q/2} \left( \max_{1 \leq j \leq p} \left( \sum_{i=1}^{p} \delta_i \|B_{i,j}\|_2^2 \right)^{q/2} \right) + \delta \|B\|_{B,1}^2$$

$$\leq 2^{1.5} \sqrt{q} \max_{1 \leq i, j \leq p} \|B_{i,j}\|_2 \mathbb{E}_{q/2} \left( \max_{1 \leq j \leq p} \left( \sum_{i=1}^{p} \delta_i \|B_{i,j}\|_2^2 \right)^{1/2} \right) + \delta \|B\|_{B,1}^2$$

$$\leq 2^{1.5} \sqrt{q} \|B_{i,j}\|_{B,2} \mathbb{E}_{q/2} \max_{1 \leq j \leq p} \|RB_j\|_2 + \delta \|B\|_{B,1}^2$$

$$\leq 2^{1.5} \sqrt{q} \|B_{i,j}\|_{B,2} \mathbb{E}_{q/2} \|RB\|_{B,1} + \delta \|B\|_{B,1}^2$$

and notice that $E$ has appeared on the right hand side. By following the same argument that ends the proof of Lemma 4, we complete the proof. \qed

4 Proof of Theorem 1

We can now prove the main theorem. Split $G$ into its diagonal blocks $D$ (containing $X_i^H X_i - I$, $1 \leq i \leq p$) and off-diagonal blocks $H$ (containing $X_i^H X_j$, $1 \leq i \neq j \leq p$) and apply Lemma 3:

$$\mathbb{E}_q \|RGR\|_2 \leq 2\mathbb{E}_q \|RR'\|_2 + \mathbb{E}_q \|RD\|_2.$$  

To estimate the first term, we apply Lemma 4 twice: once for $R$, and once for $R'$:

$$\mathbb{E}_q \|RR'\|_2 \leq 3\sqrt{q}\mathbb{E}_q \|RR'\|_{B,1} + \sqrt{\delta\mathbb{E}_q \|R'\H\|_2}$$

$$\leq 3\sqrt{q}\mathbb{E}_q \|RR'\|_{B,1} + 3\sqrt{\delta\mathbb{E}_q \|RR'\|_{B,1} + \delta \|H\|_2}.$$  

By applying Lemma 5 on the first term, we obtain

$$\mathbb{E}_q \|RR'\|_2 \leq 3\sqrt{q} \left[ 2^{1.5} \sqrt{q}\mathbb{E}_q \|HR'\|_{B,2} + \sqrt{\delta\mathbb{E}_q \|HR'\|_{B,1}} \right] + 3\sqrt{\delta\mathbb{E}_q \|HR'\|_{B,1} + \delta \|H\|_2}$$

Since $R$ and $R'$ have the same distribution, we can collect terms to get

$$\mathbb{E}_q \|RRR\|_2 \leq 9\mathbb{E}_q \|HR\|_{B,2} + 6\sqrt{\delta\mathbb{E}_q \|HR\|_{B,1} + \delta \|H\|_2} + \mathbb{E}_q \|RD\|_2.$$  

9
To bound $\|HR\|_{B,1}$, we denote $\Phi_{\{i\}}^C = [\Phi_1^H \cdots \Phi_{i-1}^H \Phi_{i+1}^H \cdots \Phi_p^H]^H$; we then have

$$\|HR\|_{B,1} \leq \|H\|_{B,1} = \max_{1 \leq i \leq p} \|\Phi_i^H\Phi_{\{i\}}^C\|_2 \leq \max_{1 \leq i \leq p} \|\Phi_i^H\Phi\|_2 \leq \max_{1 \leq i \leq p} \|\Phi_i\|_2 \|\Phi\|_2.$$

Using the Geršgorin circle theorem [7], we can show that for each $1 \leq i \leq p$ $\|\Phi_i\|_2 \leq \sqrt{1 + (m-1)\mu}$, so that $\|HR\|_{B,1} \leq \sqrt{1 + (m-1)\mu}\|\Phi\|_2$. Now we use the facts $\|HR\|_{B,2} \leq \mu_B$, $\|H\|_2 \leq \|G\|_2 + \|D\|_2 = \|\Phi\|_2^2 + \|D\|_2$ and

$$E_q \|RDR\|_2 \leq \|D\|_2 = \max_{1 \leq i \leq p} \|\Phi_i^H\Phi_i - I\|_2 \leq \mu_B$$

(from Lemma 1) to prove the theorem:

$$E_q \|RGR\|_2 \leq 9q\mu_B + 6\sqrt{\delta(1 + (m-1)\mu)}\|\Phi\|_2 + \delta(\|\Phi\|_2^2 + \mu_B) + \mu_B$$

$$\leq 20\mu_B \log(p\mu) + 9\sqrt{\delta\log(p\mu)}(1 + (m-1)\mu)\|\Phi\|_2 + \delta\|\Phi\|_2^2.$$
